CS 348 Intro to Artificial Intelligence

Day 6 Constraint Satisfaction

(slides based on Downy, Sood, Dan Klein, Pieter Abbeel)

- Class business
 - Lab 1 grades on canvas (60% of class received 100/100)
 - First resubmission due today 7pm
 - Lab 2 due Thursday
 - Lab 3 due 4/28 7pm (A*)
- Constraint satisfaction(6.1-6.6)
- Introduce lab 4 (Tic-Tac-Toe)
- Answer lab 2 questions

Homework submission

- 1 time no questions asked late submission, 143 hours extra time
 - Save for emergencies
- Please check your submitted code on NU servers
 - Simple errors need to be corrected with the first resubmission
- Feedback and testcases only provided after first resubmission deadline.
- Please don't copy any of the main.py functions / data into submitted student code.
 - Can interfere with autograder.

What is Search For?

 Assumptions about the world: a single agent, deterministic actions, fully observed state, discrete state space

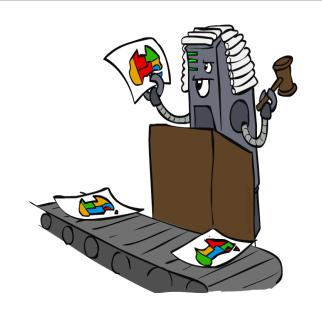

- Planning: sequences of actions
 - The path to the goal is the important thing
 - Paths have various costs, depths
 - Heuristics give problem-specific guidance
- Identification: assignments to variables
 - The goal itself is important, not the path
 - All paths at the same depth (for some formulations)
 - CSPs are a specialized form of identification problems

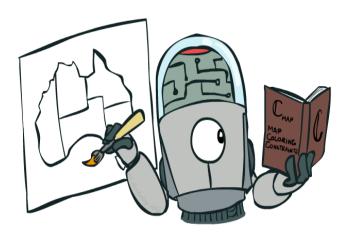

Constraint Satisfaction Problems

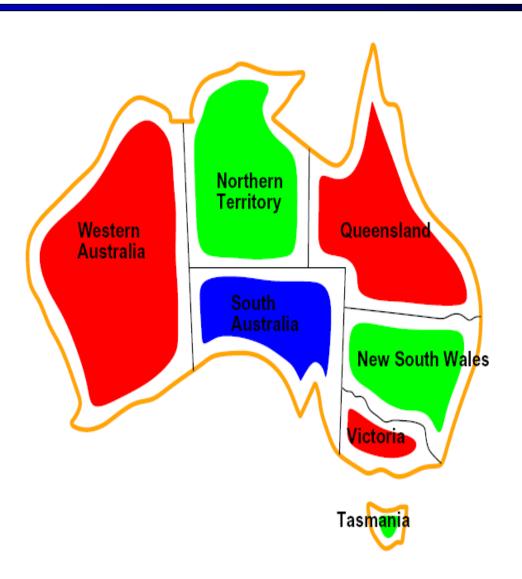

Standard search problems:

- State is a "black box": arbitrary data structure
- Goal test can be any function over states
- Successor function can also be anything
- Constraint satisfaction problems (CSPs):
 - A special subset of search problems
 - State is defined by variables X_i with values from a domain D (sometimes D depends on i)
 - Goal test is a set of constraints specifying allowable combinations of values for subsets of variables
- Allows useful general-purpose algorithms with more power than standard search algorithms

CSP Examples

Example: Map Coloring

- Variables: WA, NT, Q, NSW, V, SA, T
- Domains: D = {red, green, blue}
- Constraints: adjacent regions must have different colors

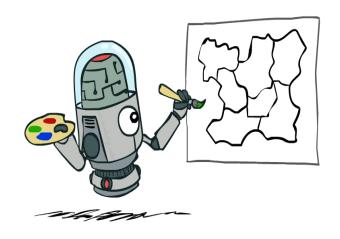

Implicit: WA \neq NT

Explicit: $(WA, NT) \in \{(red, green), (red, blue), ...\}$

Solutions are assignments satisfying all constraints, e.g.:

{WA=red, NT=green, Q=red, NSW=green, V=red, SA=blue, T=green}

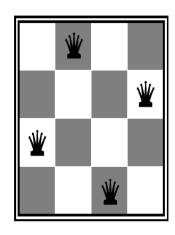

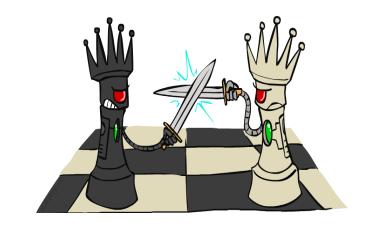

Example: N-Queens

Formulation 1:

- Variables X_{ij}
- **Domains**: {0,1}
- Constraints

$$\forall i, j, k \ (X_{ij}, X_{ik}) \in \{(0,0), (0,1), (1,0)\}$$

$$\forall i, j, k \ (X_{ij}, X_{kj}) \in \{(0,0), (0,1), (1,0)\}$$

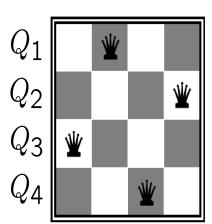

$$\forall i, j, k \ (X_{ij}, X_{i+k,j+k}) \in \{(0,0), (0,1), (1,0)\}$$

$$\forall i, j, k \ (X_{ij}, X_{i+k,j-k}) \in \{(0,0), (0,1), (1,0)\}$$

Example: N-Queens

Formulation 2:

- Variables: Q_k
- **Domains:**{1,2,3,...*N*}

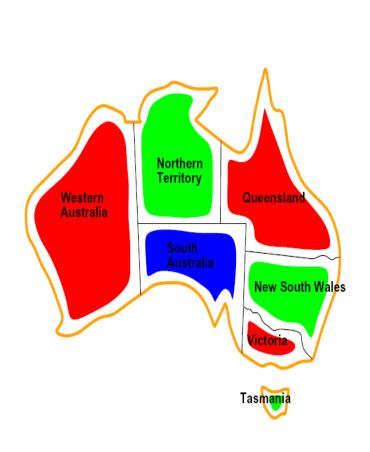

Constraints:

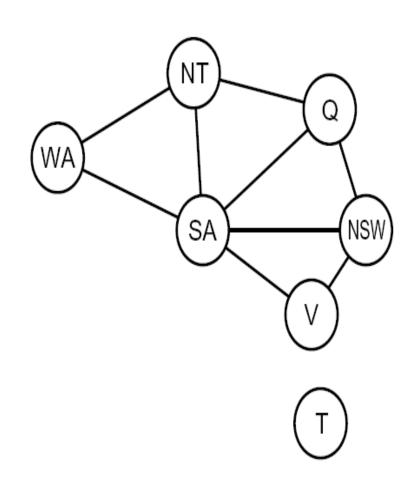

Implicit: $\forall i, j$ non-threatening (Q_i, Q_j)

Explicit: $(Q_1, Q_2) \in \{(1, 3), (1, 4), \ldots\}$

. . .

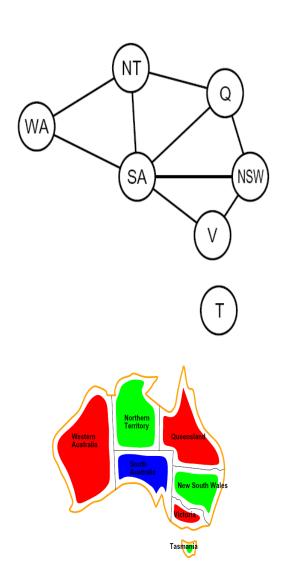

Constraint Graphs

Constraint Graphs

- Binary CSP: each constraint relates (at most) two variables
- Binary constraint graph: nodes are variables, arcs show constraints
- General-purpose CSP algorithms use the graph structure to speed up search. E.g., Tasmania is an independent subproblem!

Example: Cryptarithmetic

Variables:

$$F T U W R O X_1 X_2 X_3$$

Domains:

$$\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$$

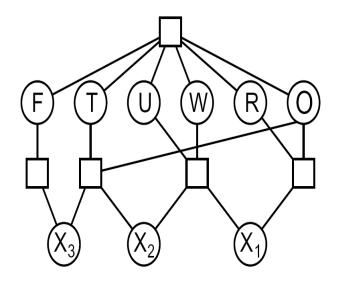

Constraints:

$$\mathsf{alldiff}(F, T, U, W, R, O)$$

$$O + O = R + 10 \cdot X_1$$

• • •

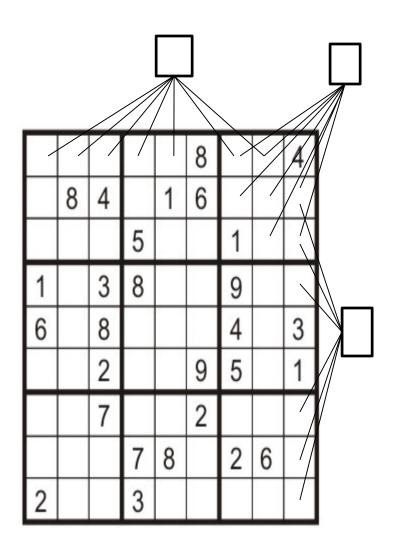

Example: Sudoku

					8			4
	8	4		1	6			
			5			1		
1		3	8			9		
6		8				4		3
		2			9	5		1
		7			2			
			7	8		2	6	
2			3					

- Variables:
- Domains:
- Constraints:

Example: Sudoku

- Variables:
 - Each (open) square
- Domains:
 - **•** {1,2,...,9}
- Constraints:

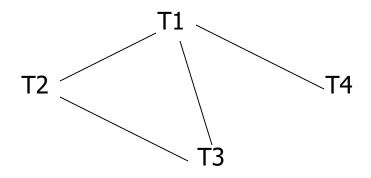

9-way alldiff for each column

9-way alldiff for each row

9-way alldiff for each region

(or can have a bunch of pairwise inequality constraints)

Example: Task Scheduling

T1 must be done during T3

T2 must be achieved before T1 starts

T2 must overlap with T3

T4 must start after T1 is complete

Varieties of Constraints

Varieties of Constraints

 Unary constraints involve a single variable (equivalent to reducing domains), e.g.:

$$SA \neq green$$

Binary constraints involve pairs of variables e.g.:

$$SA \neq WA$$

Higher-order constraints involve 3 or more variables:

e.g., cryptarithmetic column constraints

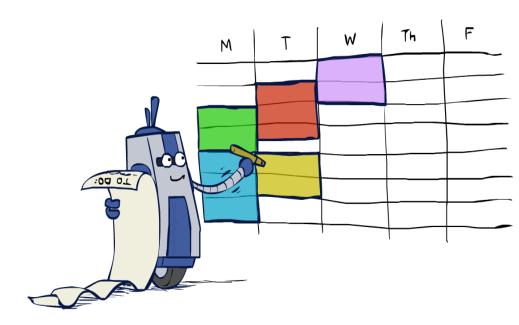

- E.g., red is better than green
- Often representable by a cost for each variable assignment
- Gives constrained optimization problems

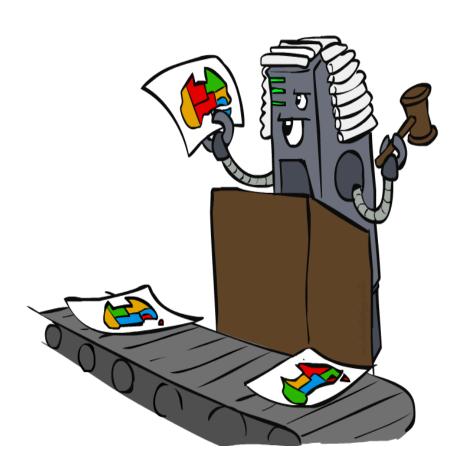

Real-World CSPs

- Assignment problems: e.g., who teaches what class
- Timetabling problems: e.g., which class is offered when and where?
- Hardware configuration
- Transportation scheduling
- Factory scheduling
- Circuit layout
- ... lots more!

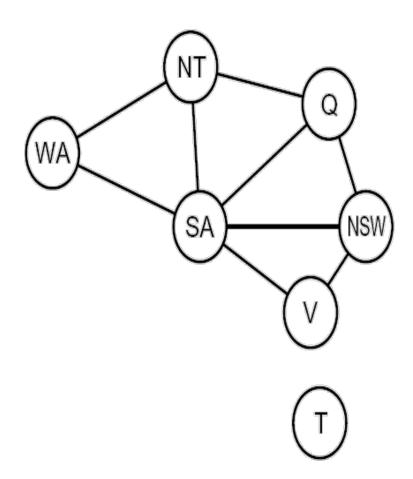

Standard Search Formulation

- Standard search formulation of CSPs
- States defined by the values assigned so far (partial assignments)
 - Initial state: the empty assignment, {}
 - Successor function: assign a value to an unassigned variable
 - Goal test: the current assignment is complete and satisfies all constraints
- We'll start with the straightforward, naïve approach, then improve it

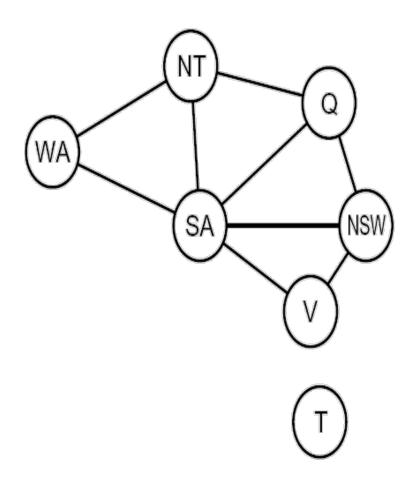

Search Methods

What would BFS do?

Search Methods

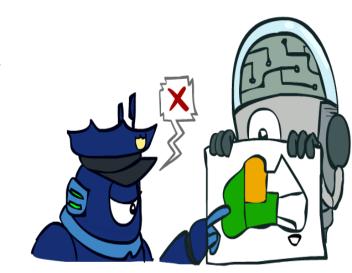

What would DFS do?

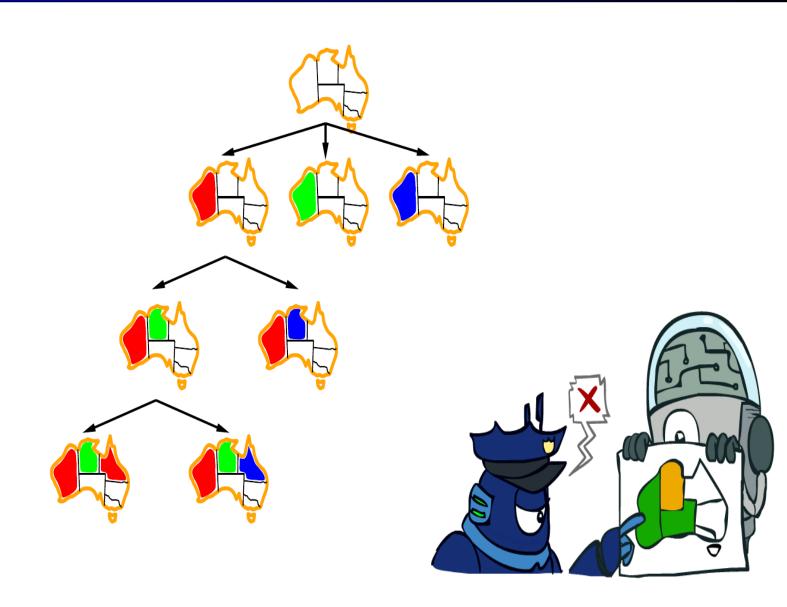

What problems does naïve search have?

Backtracking Search

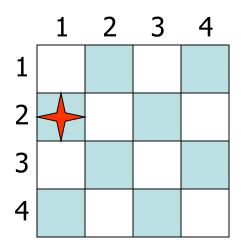

- Backtracking search is the basic uninformed algorithm for solving CSPs
- Idea 1: One variable at a time
 - Variable assignments are commutative, so fix ordering
 - I.e., [WA = red then NT = green] same as [NT = green then WA = red]
 - Only need to consider assignments to a single variable at each step
- Idea 2: Check constraints as you go
 - I.e. consider only values which do not conflict previous assignments
 - Might have to do some computation to check the constraints
 - "Incremental goal test"
- Depth-first search with these two improvements is called backtracking search
- Can solve n-queens for $n \approx 25$

Backtracking Example

Backtracking

Backtracking Search

```
function BACKTRACKING-SEARCH(csp) returns solution/failure
  return Recursive-Backtracking({ }, csp)
function RECURSIVE-BACKTRACKING (assignment, csp) returns soln/failure
   if assignment is complete then return assignment
   var \leftarrow \text{Select-Unassigned-Variable}(\text{Variables}[csp], assignment, csp)
   for each value in Order-Domain-Values (var, assignment, csp) do
       if value is consistent with assignment given Constraints [csp] then
           add \{var = value\} to assignment
           result \leftarrow Recursive-Backtracking(assignment, csp)
           if result \neq failure then return result
           remove \{var = value\} from assignment
  return failure
```

- Backtracking = DFS + variable-ordering + failon-violation
- What are the choice points?

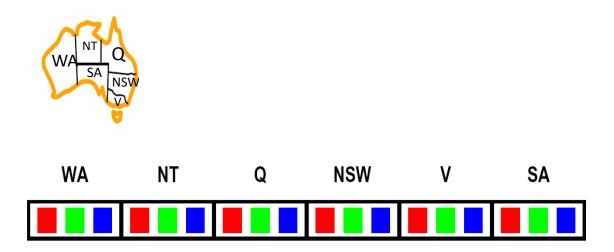

Improving Backtracking

- General-purpose ideas give huge gains in speed
- Ordering:
 - Which variable should be assigned next?
 - In what order should its values be tried?
- Filtering: Can we detect inevitable failure early?

Filtering: Forward Checking

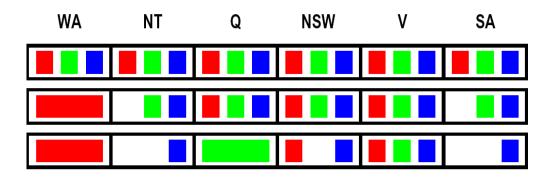

- Filtering: Keep track of domains for unassigned variables and cross off bad options
- Forward checking: Cross off values that violate a constraint when added to the existing assignment

Filtering: Constraint Propagation

 Forward checking propagates information from assigned to unassigned variables, but doesn't provide early detection for all failures:

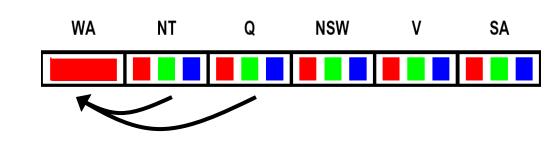

- NT and SA cannot both be blue!
- Why didn't we detect this yet?
- Constraint propagation: reason from constraint to constraint

Consistency of A Single Arc

■ An arc X → Y is consistent iff for every x in the tail there is some y in the head which could be assigned without violating a constraint

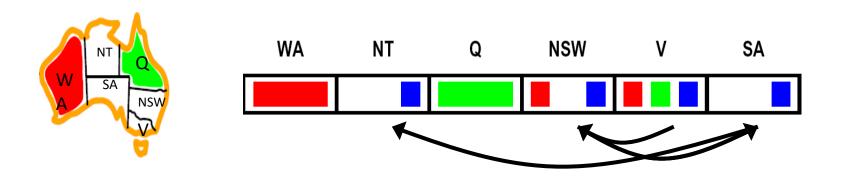

Delete from the tail!

 Forward checking: Enforcing consistency of arcs pointing to each new assignment

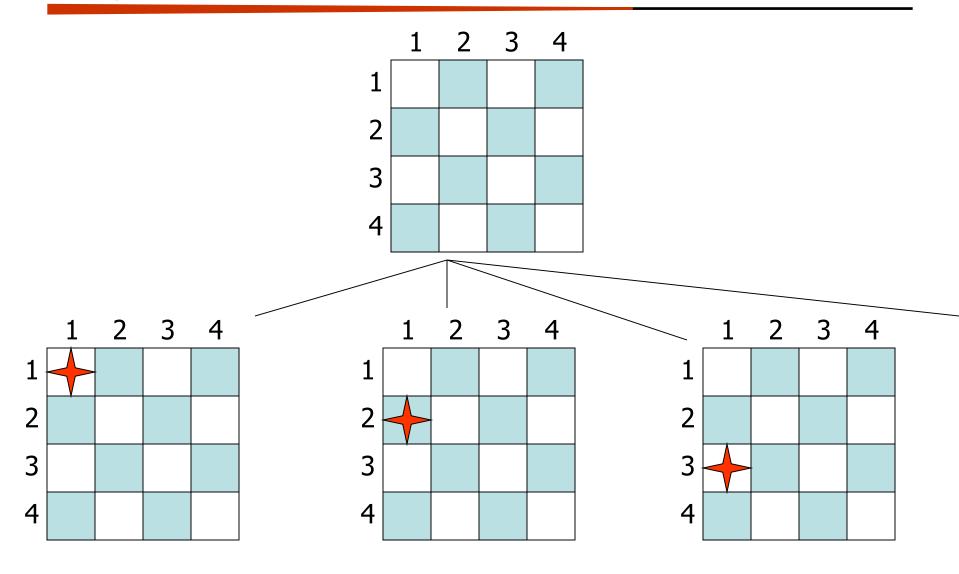

Arc Consistency of an Entire CSP

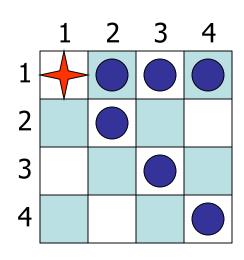

A simple form of propagation makes sure all arcs are consistent

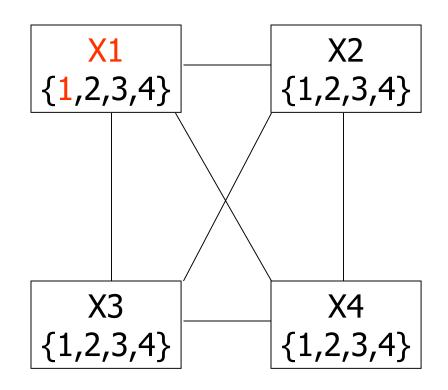

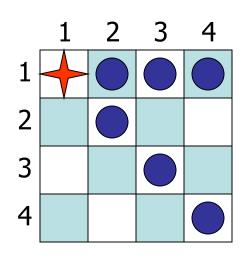

- Important: If X loses a value, neighbors of X need to be rechecked!
- Arc consistency detects failure earlier than forward checking
- Can be run as a preprocessor or after each assignment

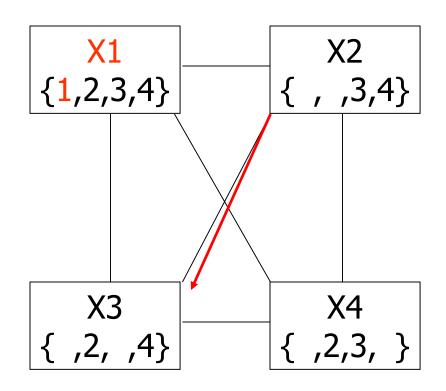

Remember: Delete from the tail!

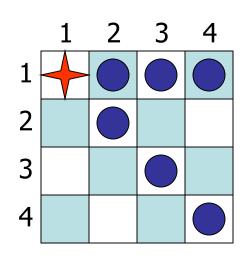

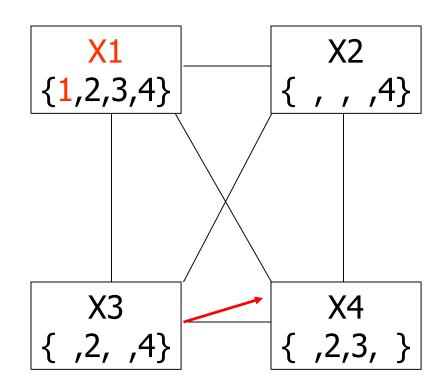

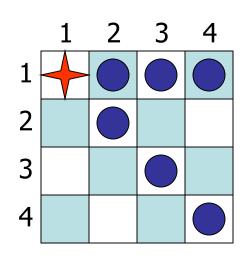

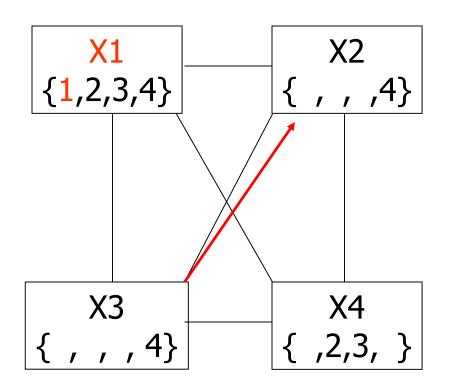

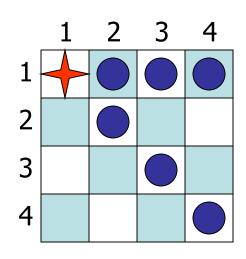

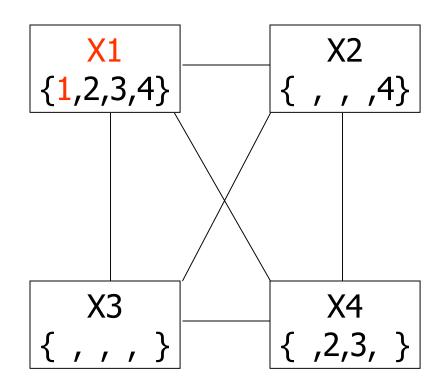

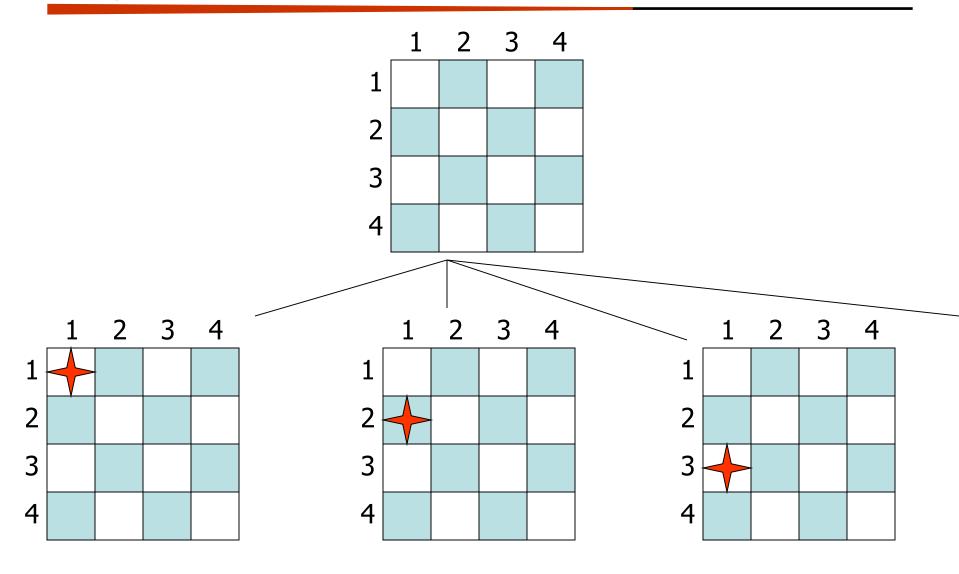

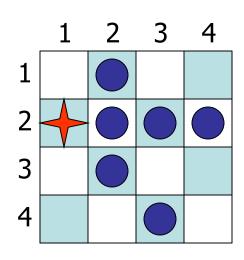

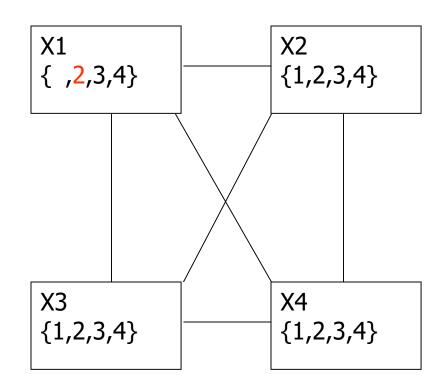

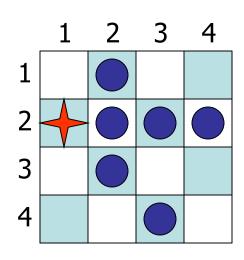

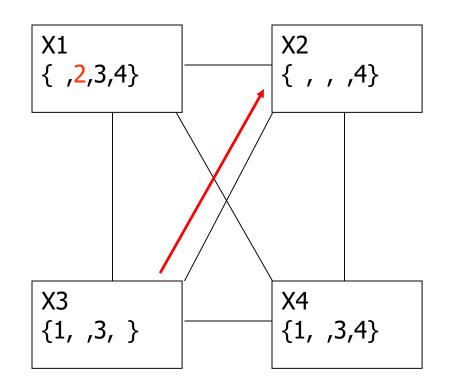

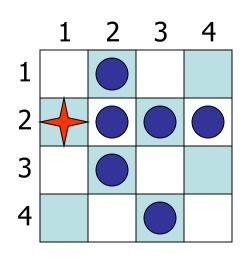

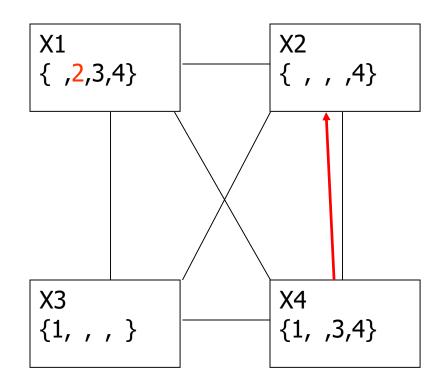

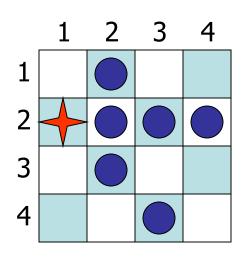

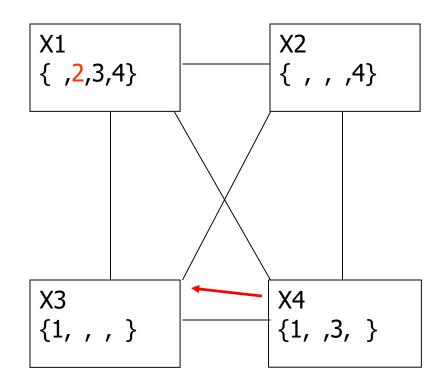

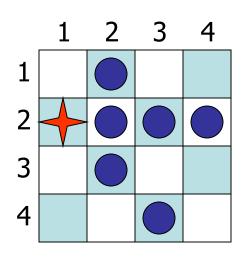

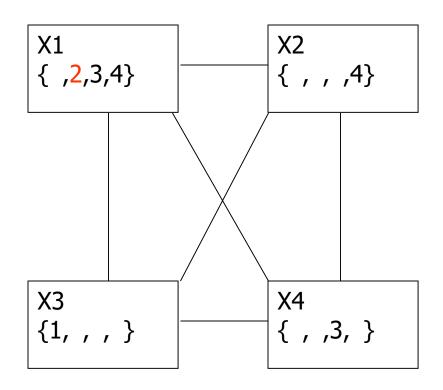

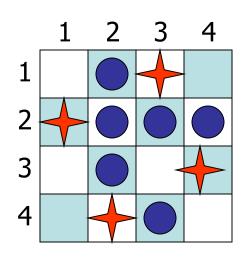

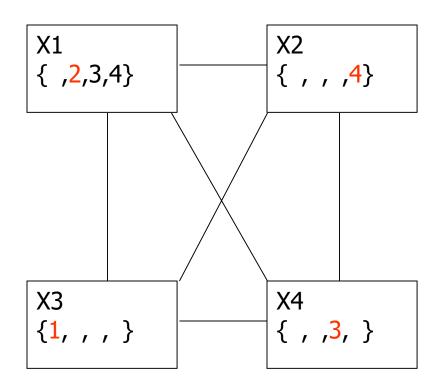

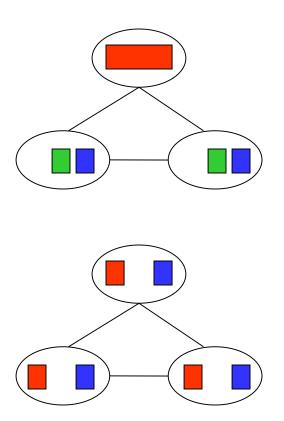

Limitations of Arc Consistency

- After enforcing arc consistency:
 - Can have one solution left
 - Can have multiple solutions left
 - Can have no solutions left (and not know it)
- Arc consistency still runs inside a backtracking search!

What went wrong here?

Backtracking Search

```
function BACKTRACKING-SEARCH(csp) returns solution/failure
  return Recursive-Backtracking({ }, csp)
function RECURSIVE-BACKTRACKING (assignment, csp) returns soln/failure
   if assignment is complete then return assignment
   var \leftarrow \text{Select-Unassigned-Variable}(\text{Variables}[csp], assignment, csp)
   for each value in Order-Domain-Values (var, assignment, csp) do
       if value is consistent with assignment given Constraints [csp] then
           add \{var = value\} to assignment
           result \leftarrow Recursive-Backtracking(assignment, csp)
           if result \neq failure then return result
           remove \{var = value\} from assignment
  return failure
```

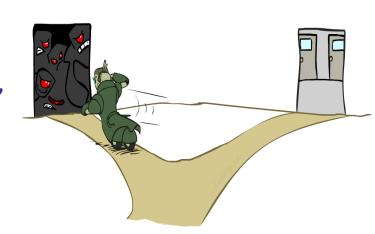

- Backtracking = DFS + variable-ordering + failon-violation
- What are the choice points?

Ordering: Minimum Remaining Values

- Variable Ordering: Minimum remaining values (MRV):
 - Choose the variable with the fewest legal left values in its domain

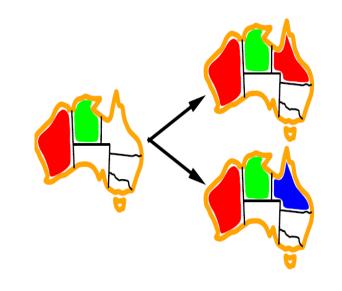

- Why min rather than max?
- Also called "most constrained variable"
- "Fail-fast" ordering

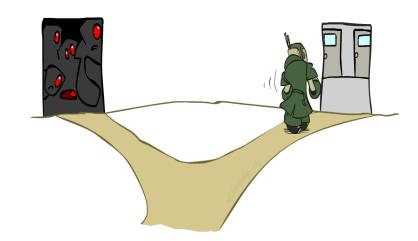

Ordering: Least Constraining Value

- Value Ordering: Least Constraining Value
 - Given a choice of variable, choose the least constraining value
 - I.e., the one that rules out the fewest values in the remaining variables
 - Note that it may take some computation to determine this! (E.g., rerunning filtering)

 Combining these ordering ideas makes
 1000 queens feasible

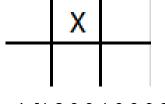

Summary

- CSP's
 - Uninformed search
 - Backtracking
 - Forward checking
 - Heuristic for expansion order
 - MRV
 - LCV

Lab 4 Due May 6, 7pm

- Create a TIC-TAC-TOE solver capable of predicting the result of a specific game when a board is provided.
- Complete 2 Functions
 - minmax_tictactoe(board, turn)
 - abprun_tictactoe(board, turn)

board=[1,2,0,0,1,0,0,0,0]

- Must use game_status(board) to check board
 - Use once per node in search tree

Lab4

- AB pruning must use exact algorithm from day 4 slides
 - Don't use any additional information about game to improve it
- Helpful hint:
 - AB pruning code can be turned into mini-max with a very simple modification.
 - Must work for any board state, even those not reachable in standard play
- Program in python3
- Don't use any additional modules other than the included common

Lab 2 questions?
